System Description

The Neuron.THC torch height control system is the full standalone most technologically advanced arc voltage control system in the plasma cutting industry. It is designed to offer arc voltage control capabilities to any plasma cutting system. The Neuron.THC quickly and accurately sets the arc transfer height of the torch using an “Ohmic” or/and “Float Head” plate sensing technique. The Neuron.THC system uses software servo control loops to control speed, position and arc voltage with unparalleled precision.

The Neuron.THC can attain speeds in excess of 6000 mm/min (250 inches per minute) in the arc voltage control mode and speeds in excess of 10000 mm/min (400 inches per minute) in the position control mode.

Safety

The Neuron.THC system use D.C. for operation. In addition, it will be necessary to make connections to the D.C. output of the plasma power supply. These voltages can be in excess of 300 volts. Fatal shock hazard does exist. Exercise extreme caution while working in these areas. Please refer to the plasma power supply manufacturer’s operating manual for additional information.

Various other safety hazards exist while operating a plasma arc cutting system. Please see the plasma power supply manufacturer’s operating manual for information on eye, skin, and hearing protection, as well as other information required to safely operate the equipment.

System Components

The Neuron.THC System consists of the following components:

- Control module
- Plasma interface PCB
- CNC interface PCB
- Motor driver interface PCB

Control module

The control module houses a microcontroller, and I/O interface. This unit provides arc voltage control, and interfaces with the torch driver through the Pulse/Direction interface, the CNC machine through the discrete I/O interface, and the plasma system through standard discrete I/O interfaces.

Plasma system interface PCB

It provides precise, scaled feedback of the plasma arc voltage to the control module. It also provides a convenient control signal interface to the Neuron.THC.

CNC interface PCB

The module provides discrete I/O interface between THC and CNC.

Motor driver interface PCB

The module provides easy connection to the motor driver.

Signals from/to plasma source to control module interface:

- Arc voltage: 0-12.5V (20:1 input) or 0-350 V - input
- Start plasma (Normal Open Relay Contact 100 mA protected) - output
- ArcOK (Transfer) - input

Signals from/to CNC to control module:

- Cycle Start input. The Neuron requires a 5V DC sourced signal on this input to start the cutting sequence. Polarity is not important.
- THC OFF input. The Neuron requires a 5V DC sourced signal on this input to disable arc voltage control during automatic operation. Polarity is not important.
- Motion output. The Neuron provides a relay contact closure on this output after it completes the pierce delay time and moves the torch from the pierce height to the cutting height. Normal Open relay contacts 100 mA protected.

**NOTE:** All THC I/O signals has full galvanic (optocoupler) isolation.

Control module has a size 115x90x45 mm with DIN mounting standard.
Plasma interface PCB (voltage divider)
Features

The Neuron.THC comes standard with the following features:

- Single chip computer based compact control, industrial grade protection, easy to install almost anywhere
- Digital display and set arc voltage and other parameters, easy to learn and operate
- Works with ALL plasma cutters
- Controls Z axis directly (Internal motion controller, Software PID control loop)
- 30 cut profiles for different metal thicknesses. Quickly switch between profiles and the ability to quick edit them
- Set point voltage range 25 - 250V
- Set Point voltage resolution 0.5V
- Maximum control accuracy +/- 0.25V
- Height control accuracy +/-0.125 mm (.005") using a properly configured Z-axis.
- Works in Inches or Millimeters mode
- Automatic or manual control of the cutting sequence
- “Sample and Hold” voltage mode - THC measures the voltage at the end of the AVC Delay and uses it as a set point for the remainder of the cut.
- Automatic Collision Avoidance, provided that the Ohmic sensor is used. This safety feature allows the control to automatically adjust the torch height during a cut to help prevent torch crashes
- THC OFF control from CNC (on corners, end of cut, circle of small radius)
- Programmable arc voltage limiter Lock Head Down to help prevent torch crashing when crossing a kerf, corner, end of cut
- Programmable arc voltage control loop dynamic (gain) value
- Shot mode – can use for marking centers of the circles
- Works with Float Head and Ohmic sensors for IHS simultaneously
- Built in Testing of the cutting sequence
- Integrated diagnostic system informs the operator of the errors that occurred
- Programmable automatic positioner speed
- Programmable jog positioner speed
- Programmable IHS (initial height sensing) touch speed
- Programmable acceleration
- Programmable arc transfer height
- Programmable pierce height
- Programmable pierce time
- Programmable cutting height
- Programmable AVC (automatic voltage control) delay time
- Programmable crossover (IHS start) height (high-to-low speed transition point)
- Programmable torch retract height
- Programmable torch retract delay
- Programmable maximum torch slide length (Soft Limit)
- Easy setup for Float Head switch offset value
- Improved Jog - the lifter initially jogs 0.25 mm. After 0.5 second, it begins continuous motion at the IHS Speed. After 1.5 seconds, the lifter increases the speed to the programmed Manual Speed
- Voltage feedback (divider) - Raw arc voltage divider (houses on the plasma interface board) or 1:20 (input for Hypertherm cutters)
- 50 kHz maximum step frequency 50% duty cycle.
- Buffered Step & Direction outputs for direct interface to Motor Drive
- All inputs (include arc voltage) are isolated and simple wiring (RJ45 connectors)
System Requirements

The Neuron.THC system has a terminal block power plug. 12V DC 0.5A required. Do not use 12V power from CNC PC! Use separated power supply.

The performance of the Neuron.THC is tightly coupled to the lifter and motor characteristics. The Neuron.THC was designed as a conventional plasma height control and the lifter does not include any position feedback. The lifter screw pitch affects the lifter linear speed and the control loop gain when operating with arc voltage. The lifter friction and maximum torch weight affect the point at which the lifter will require a brake to maintain position. For these reasons, the motor and lifter characteristics are critical and must be tightly controlled.

The following is a partial list of lifter and motor characteristics that are compatible with this controller.

- Lifter Ball screw/Rack pitch = 4 – 20 mm/rev
- Lifter with UP limit (homing sensor), Probe sensor (Float torch holder) for Initial Height Sensing procedure.
- Lifter capable of 200 in/min.
- Lifter should have low backlash and little mechanical play
- If the functions are required the lifter should provide for the electrical interface to torch tip sensing.

WARNING:

The performance of the Neuron.THC is tightly coupled to the lifter and motor characteristics. To ensure proper operation, a customer designed lifter should be fully tested with this controller under all anticipated operating conditions.
### Electrical Connection

#### Block diagram of system

This diagram shows the basic I/O interface of the Neuron.THC system to plasma cutter, CNC, torch slide and motor driver. To the main control module connects plasma cutter discrete I/O PCB (voltage divider), CNC interface PCB and motor driver interface PCB through Cat5e cable crimped pin to pin on RJ45 plugs. Torch slide sensors (homing, float head and ohmic (optional)) are connected to the screw terminals on the main control module PCB.

![Block diagram of system](image)

**NOTE:** Ohmic input is optional for different versions of the controller PCB.

**NOTE:** All interconnection RJ45 Cat5e cable has the PIN TO PIN connection.
Lifter Input signals interface schematic (home, float head and ohmic)

Motor driver differential interface schematic

Optocoupler input is the best available option in terms of resistance to interference and convenience of connection. For each signal, twisted pair of cables is needed. If motor driver has optocoupler inputs then there is no need to connect GND of the devices too.

Proper connection to optocoupler inputs

Signs on the drive may differ so you should first read the documentation carefully. It can be e.g. PUL+/PUL- and SIGN+/SIGN-, however it is not a rule. Servo drives often have two different types of STEP/DIR inputs.

There is connection variant with shared (common) GND wire. This variant (most Gecko microstep drivers) is a little bit worse because of lower interference resistance and it is a bit more difficult to connect.
In this case, we do not use twisted cable and that is why the connection is more exposed to the influence of interferences.

**It is important to do not connect STEP- and DIR- pins with GND of the device because it will cause short circuit and output stages damage.**

There is a special PCB for connecting Neuron differential Step/Dir output to the motor driver.

Set JP1, JP2 jumpers to 1-2 pins for differential connection:

Set JP1, JP2 jumpers to 2-3 pins for shared ground connection:
1. Mount the Neuron.THC control module.
2. Connect Home and Initial Height Sensing (Float Head and/or Ohmic Sensor) switches to screw terminals on the Control Module.
3. Connect CNC interface PCB to the “CNC Interface” RJ45 socket on the Control Module.
4. Connect the plasma cutter interface PCB to the “Plasma Interface” RJ45 socket on the Control Module.
5. Connect the Torch Lifter Driver to Pulse/Direction to the “Motor Driver” RJ45 socket on the Control Module.
6. Connect the power supply (DC 12 volt / 0.5A) to screw terminals on the Control Module.

**NOTE:** All interconnection RJ45 Cat5e cable has the PIN TO PIN connection.

Pins 10-13 and 15 are inputs. Only these 5 pin numbers may be used on this screen.
Configure Mach3 Output signals:

For THC OFF control from G-Code use SheetCamTNG rules. Install SheetCam Tools file downloaded from our website. Use Mach3PlasmaNoZ postprocessor.

- Configure Output#1 signal to port1 pin9 for CYCLESTART
- Configure Output#5 signal to port1 pin8 for THC OFF control
- Configure THCON input to port1 pin15 for Motion signal from controller.

NOTE: Depend from used BOB you have to setup ActiveLow properties for used pins.

Connection diagram for Mach3 CNC to the Neuron BOB
Configure Mach3 Output signals:

- Configure Output#1 signal to port1 pin1 for CYCLESTART
- Configure Output#5 signal to port1 pin16 for THC OFF control
- Configure THCON input to port1 pin15 for Motion signal from controller.

Configure Mach3 Input signals:
Recommended grounding and shielding practices

Introduction

Make sure that the machine is properly grounded. Plasma cutters generate voltage dangerous for human health and life. No grounding may result in electric shock and / or damage electronic equipment.

This chapter describes the grounding and shielding necessary to protect a plasma cutting system installation against radio frequency interference (RFI) and electromagnetic interference (EMI) noise. It addresses the three grounding systems described below.

Note: These procedures and practices are not known to succeed in every case to eliminate RFI/EMI noise issues. The practices listed here have been used on many installations with excellent results, and we recommend that these practices be a routine part of the installation process. The actual methods used to implement these practices may vary from system to system, but should remain as consistent as possible.

Types of grounding

1. The safety, protective earth (PE), or service ground. This is the grounding system that applies to the incoming line voltage. It prevents a shock hazard to any personnel from any of the equipment, or the work table. It includes the service ground coming into the plasma system and other systems such as the CNC controller and the motor drivers, as well as the supplemental ground rod connected to the work table. In the plasma circuits, the ground is carried from the plasma system chassis to the chassis of each separate console through the interconnecting cables.

2. The DC power or cutting current ground. This is the grounding system that completes the path of the cutting current from the torch back to the plasma system. It requires that the positive lead from the plasma system be firmly connected to the work table ground bus with a properly sized cable. It also requires that the slats, on which the workpiece rests, make good contact with the table and the workpiece.

3. RFI and EMI grounding and shielding. This is the grounding system that limits the amount of electrical “noise” emitted by the plasma and motor drive systems. It also limits the amount of noise that is received by the CNC and other control and measurement circuits. This grounding/shielding process is the main target of this document.

Steps to take

1. All motor and drive related leads need full shielding and twisted pair connectors. The shields should all be connected back to a star ground point at the driven ground rod.

2. Torch leads need to be shielded (outer cover with braided metal shield) that should be grounded only at the high frequency generator end.....back to the star ground point. The rest of the leads must be isolated from any machine metallic parts....preferably inside a plastic nonconductive power track.

3. Chassis of plasma power supply (with high frequency generator should be mounted away (as far as practically possible) from the PC, and should be grounded directly to the star ground point.

4. PC should be as far away from the plasma power supply, should get its AC sourced through an uninterruptible power supply with surge protection. PC chassis should be grounded directly to the star ground point.

5. If a remote wired pendant is used, it should have a shielded cable, also grounded to the star ground point.

6. The gantry of the cutting machine should be grounded to the star ground point.

7. The torch carriage and z axis slide should be grounded to the star ground.
8. The computer monitor should be connected to the computer with a shielded cable. The mouse also needs to be shielded.

Note: each ground wire to the star ground needs to be separate.....no "daisy chainning" as this can create ground loops.

The work ground from the plasma should be bolted directly to the star ground (no welding clamp)

The cutting slat bed should be connected directly to the star ground as well.

The star ground point should be right on the ground rod, or within about 6 feet, any extra cable length should be shortened, no cables on the machine should have any coiled extra length.

Voltage Divider Installation - General

!!!! WARNING !!!!
TURN OFF ALL POWER BEFORE WORKING ON EQUIPMENT

The voltage divider provides a feedback signal which is derived from the actual cutting arc voltage of the plasma power supply. The Neuron.THCP control uses this feedback signal to control the cutting height of the torch. The voltage divider used in the Neuron.THCP a 10:1 signal. This simply means that a cutting voltage of 100 volts results in a signal of 10 volts provided to the control. The power supply positive and power supply negative connections on the voltage divider should be connected to the proper output points of the plasma power supply.
Powermax cutter. Internal divider 20:1

Установите переключатель в показанное положение, что соответствует коэффициенту деления 20:1
set JP1, JP2 jumpers to 1-2 pins

ARC VOLTAGE SENSE WIRES
USE 18AWG (~0.9 MM SQUARED)
TWISTED PAIR WIRE, RATED 600V OR GREATER

set JP1, JP2 jumpers to 2-3 pins

Hypertherm CPC connector

Plasma Start - 3,4 pins
ArcOK (Transfer) - 12,14 pins
Other plasma unit. Onboard divider.

Please check marking on the sensor PCB for correct connections.

Set JP1, JP2 jumpers to 2-3 pins.

Arc voltage sense wires. Use 18AWG (~0.9 mm squared) twisted pair wire, rated 600V or greater.
Setup Main module.

Set jumper for setup divider ratio for arc voltage input.
### Controls

- Press and hold the “THC MODE” button for entering to the setup menu.

- When profile select menu will be appear release “THC MODE” button. “ESC MENU” LED will flash.

- Press Torch UP/Down buttons to navigate to a parameter.
- Press the THC MODE button to enable a change in parameter.

- Press SP.VOLTS +/- buttons for change the parameter.
- Press again THC MODE button to return from submenu.
- Press and hold THC MODE button to exit from setup menu and store the parameter in the operator interface.
Set-Up of Cutting Sequence

Parameters

NOTE: Default unit is mm. To change to inches, first change the units. Controller has two independent profiles and general settings data bases for mm and inches systems. If you change units, please check all parameters.

The cutting profile setup menu allows you to set up the following parameters:

Set Point Voltage

The Neuron.THC system maintains the Set Point Voltage during a cut in the Auto mode. Raising the Set Point Voltage will increase the torch height during a cut, while lowering it will decrease the cutting height of the torch. The Set Point Voltage can be adjusted from 50 to 250 volts in 0.5 volt increments.

Pierce Height

This value determines the height at which the torch pierces the workpiece.

Pierce time

This is the value for the Pierce Time. During this time, the X/Y cutting motion is delayed to allow the plasma to fully pierce the workpiece.

Cut Height

This value for the height at which the torch cuts the workpiece, but before then AVC closed loop control will be started (if AVC ON).

AVC Delay

This value sets the number of seconds that are required for the cutting machine and plasma torch to achieve steady-state operation at the cut height. After this delay, the AVC is enabled for the remainder of the cut.
THC Dynamic

This gain is used when the THC is operating closed-loop arc voltage control. How to use: If this value is set too high, the lifter positioning during closed-loop arc voltage control will become unstable and prone to oscillation. If this value is set too low, the arc voltage control can become slow and inaccurate. The value of 7 is appropriate.

The THC Response can be tested by change value during cutting under closed-loop arc voltage control and checking that the THC quickly and accurately reaches the set arc voltage.

Very high speeds on very thin or highly warped metal may require increasing the Response setting to respond faster. Be careful to not go so high the torch overshoots and oscillates up and down. Remember you will generally want to go back to 7 normal cutting. To optimize this response, raise this value until a very slight oscillation is detected during a cut and then reduce the setting by 1 or 2.

Lock Head Down Level

This feature avoids that the plasma torch moves down which arc voltage is up (for example on the end of cut, when crossing a kerf or hole or going off the edge of the plate). If the adjustable Lock Head Down Level exceeds the limit during cutting, the clearance control will be disabled.

**Note:** For disabling this future set the Lock Head Down Level to lower then 4 value.

Retract Height

This parameter specifies height above the workpiece to which the torch retracts at the end of a cut.

**Note:** for set full retract mode set the Retract Height value more than 60 mm (2.5 in).

Transfer Height

This value determines the height above the workpiece where the torch is initially fired. It is the torch height after an IHS and is entered as a percentage of the Cut Height.

This setting can be used to improve the ability of the torch to transfer to the workpiece for processes that use a very high Pierce Height or have difficulty in transferring.

SHOT mode

This mode can be used to marking (for example make small corner on the centers of the holes). When the CNC issues Cycle Start signal, the controller turns on the cutter. After receiving the ArcOK (transfer) signal from the plasma supply starts “Torch ON” delay timer. When the delay timer will end, controller turns off the cutter. If SHOT mode enabled, controller will make request for “Torch ON” time (0 – 10 sec).

Testing Mode

This mode allows starting test of the cutting sequence procedure.

THC Control Mode (Voltage control/Sample voltage)

This menu allow to select THC mode – Voltage control mode (SET.U) or Sample voltage mode (SET.H).

When Sample Voltage is ON (SET.H), the THC measures the voltage at the end of the AVC Delay and uses it as a set point for the remainder of the cut. When Sample Voltage is OFF (SET.U), the “Set Point Voltage” is used as the set point for torch height control.
Display in IDLE mode:

**Set Point Voltage mode.** Operator can change set point arc voltage value by “SP.Voltage+/-” buttons.

**Sample Voltage mode.** Operator can change “Cut Height” value by “SP.Voltage+/-” buttons.

**Configuration Menu**

Push on the THC MODE button to enter to configuration menu. See Setup main controller settings.

**Start Homing (reference) menu**

This menu allow to start homing procedure. Select “YES” and exit from menu. Controller will start Homing procedure.

**Setup main controller settings**

**Parameters**

The basic configuration menu allows you to set up the following parameters:

<table>

</tbody>
</table>

**IHS Start Height**

This is the height above the last known workpiece position that the THC switches from Automatic speed to the slower IHS speed. This height should be set high enough to avoid contacting the workpiece.

**Transfer time**

This is the number of seconds that the controller will wait for transfer before attempting a retry.
Retract delay
The Retract Delay time is the time between the removal of a start signal and the retraction of the positioner. In this case the plasma power supply turn off immediatly, then delay timer will start. After finishing of the delay Motion signal will off and retraction of the torch will start. This future for example can use for disabling plasma power supply before end of cut (few tens of milliseconds) for reducing divots.

Dead Band
This value is an interval of an arc voltage where no AVC occurs.

Automatic Speed
This speed is used for all automatic rapid moves such as the End-of-Cut-Retract or the Initial Approach to the workpiece. This value depends on the lifter motor speed, the screw pitch, the weight of the lifter load and the desired speed of operation.

Jog Speed
Jog speed is the speed at which the positioner moves when operator push on the Torch UP/DOWN buttons. Note, the positioner moves at an IHS speed when the up/down buttons are initially pressed. The speed is increased to the jog speed if the buttons are held down.

IHS Speed
This parameter sets the slow speed for the final approach to the workpiece during an IHS operation. It is also used as the slow speed for jog moves.

Acceleration
This acceleration is used for all automatic, manual, IHS moves end arc voltage closed loop control. This value depends on the motor parameters, the weight of the lifter load and the desired speed of operation.

Automatic Collision Avoidance
This safety feature allows the control to automatically adjust the torch height during a cut to help prevent torch crashes. If automatic collision avoidance is enabled, the arc voltage is automatically increased any time when contact is sensed between the torch and the plate, provided that the Use Ohmic function is enabled. If the torch contacts the plate while a Hold signal is applied, the torch retracts to the programmed Cut Height, provided that the Use Ohmic function is enabled. Allowed modes on collision – Stop cutting – Ignore collision – ACA.

Float head offset setup
This function allows to setup offset for float head switch.

Slide Length setup
This value is the length of the lifter’s usable travel (Soft Limit function).
Preflow In IHS (enable/disable)

This menu allows enable/disable preflow in IHS if using ohmic sensor on the water table.

If you keep the water low enough so it does not splash mass quantities on the torch, then ohmic will work fine with a water table. If water gets on the surface of the material, expect the ohmic sensor to sense the surface of the water, not the metal. If water gets back inside the torch, often it will cause a false sense as well as it shorts from the shield to the nozzle internally. The water in a water table becomes full of suspended solids of the metal you are cutting which raises the conductivity of the water. Enable the “Preflow in IHS” mode to activate the torch postflow before sensing the material and to make the ohmic function work better with high water levels. This blows water out of the torch and keeps water away from the sensing area. If Preflow in IHS will enabled, controller make request for “Torch ON” time (0.1-10 sec). Usually 0.2 second value is OK.

Pulses in unit integer part

The value is based on the counts of pulses for motor driver. It is equal to the number of pulses in the one unit (millimeters or inches). For example slide has 5.08 mm pitch screw and on the motor driver set 1000 pulses per one motor shaft revolution value. Pulses in unit will be \( \frac{1000}{5.08} = 196.850 \)

You have to set pulses in unit integer part value to 196.

Pulses in unit decimal part

The value is based on the counts of pulses for motor driver. It is equal to the number of pulses in the one unit (millimeters or inches). For example slide has 5.08 mm pitch screw and on the motor driver set 1000 pulses per one motor shaft revolution value. Pulses in unit will be \( \frac{1000}{5.08} = 196.850 \)

You have to set pulses in unit decimal part value to 850.

NOTE: after changes pulses in unit value Slide Length and Float head offset setup required.

Reverse direction

This menu allows changing the polarity for Direction signal (for reverse motor direction). Please note that motion direction is also related to motor-driver wiring match. Exchanging the connection of two wires for a coil to the driver will reverse motion direction.

Inches/Millimeters setup

This menu allow to change of units (mm/inches)

NOTE: controller has two independent profiles and settings databases for mm and inches. If you change the units, check all settings and make initial setup of the controller motion engine.

Cutting sequence LEDs

During operation, indicates the position within the control sequence.
During set up, indicates the selected parameter.

- AVCOFF led indicates that the Automatic Voltage Control (AVC) is OFF.

In IDLE mode indicates:
- **IHS led**: show state of the IHS input (float head or ohmic sensor).
- **TRNSF LED**: show state of the ArcOK (Transfer) input.
- **AVCOFF LED**: show state of the THC OFF input.
- **IDLE LED**: show the state of the Home input.
Requirements and Check List for first Start-up

<tr>
<td>4.</td>
<td>Is the power supply (+ 12V/0.5A) of the Neuron THC System installed properly?</td>
<td></td>
</tr>
<tr>
<td>5.</td>
<td>All shields of cables going to the plasma source should not be connected at the plasma source. They must be connected in the control cabinet with the shortest possible connection to the machine ground.</td>
<td></td>
</tr>
</tbody>
</table>

Power Up

1. Power off plasma cutter.
2. Push on the “TORCH UP/DOWN” buttons and hold, then switch on controller power supply.
3. Controller will switch to the initial setup and diagnostic mode. Display will show state of the inputs. Also controller will activate/deactivate outputs signals for checking (1.5 sec On/Off period). Push on the “Torch DOWN” or “SP.VOLTS -” for select input (lower segment), then push on the “SP.VOLTS +” for change “ActiveLow/ActiveHigh” properties for selected input (upper segments).

In the IDLE mode all sensors is triggered off. Change “ActiveLow/ActiveHigh” properties for set “triggered off” state on the display (upper segments).

For example, in this picture shows the state of the controller inputs. Homing input has active state (triggered on) and has selection for change ActiveLow/ActiveHigh. Also ArcOK input has active state too.

4. Push on the “THC MODE” button to exit from this mode.
5. Controller will start homing procedure. Check, that the torch move UP to homing switch. If direction is wrong, push on the TORCH UP or DOWN button to terminate homing procedure. Error (Er.01 - Fail go to home) will issue. Push on the “THC MODE” button to clear Error.

6. Enter to the configuration menu.

7. If torch move direction during homing procedure was incorrect, set reverse motor direction in the “Reverse direction” menu.

8. Select mm or inches system. After exit from mm/inches menu controller will reboot.

9. After the reboot an initialization process runs for approx. 2 s. – The LED screen at the main control module show “BOOT” message. If the LED screen shows error, check the error table in Chapter Trouble-Shooting.

10. If all is correct controller show “PUSH” message for start homing procedure. Push on the “THC MODE” button for starting. The torch slide automatically moves to the upper reference position.

11. Enter to the configuration menu.

12. Setup integer part and decimal part of the “StepInUnit” value.

13. Setup the maximum values of the acceleration and Automatic, Jog, IHS velocities values of the torch moving as your system allowed (avoid lost steps for steppers motors).

14. Push and hold “THC MODE” button to exit from configuration menu and save configuration.

15. Power OFF controller.

16. Power ON controller.

17. Enter to the configuration menu.

18. Setup Slide Length value.

19. Setup Float Head offset value. Put on the table plate, thickness not less 3 mm.

   19.1 Push on the THC Mode button for entering to the Float Head offset setup menu.

   19.2 Select YES by “SP.Voltage+/-” buttons and push on the “THC MODE” button to start procedure.

   19.3 Controller will start Initial Height Sensing procedure. When the IHS will be completed the torch will be moved up on the 4mm for metric system or 0.2 in for inches system under surface of the plate. Check the distance between the surface of the plate and torch nozzle. If it’s not 4mm (0.2 in.) (check it for example by standard drill) correct it by TORCH UP/DOWN buttons.

   19.4 Push on the THC MODE button to exit from submenu.

20. Setup IHS Start Height, Transfer Time, Retract Delay, Dead Band to desired values.

21. Push and hold “THC MODE” button to exit from menu and store values in the operator interface.
Cutting sequence test

You can make cutting sequence test procedure for control all settings.

1. Push and hold THC MODE button to go in the cutting setup menu. Navigate to “TEST” submenu.
2. Push “THC MODE” button to enter to Cutting sequence Test submenu.
3. On the display will appear current torch position. For starting push “SP.VOLTS +” button.
4. Controller will start Initial Height Sensing procedure.
5. Push on the “SP.VOLTS +” button to go to next cutting state.
6. After then Retract state will complete, controller finished testing and exit from submenu.
### System Control State

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>IDLE</strong></td>
<td>In this state, the plasma system is OFF. The system waits for the Cycle Start input signal from CNC and enters either the IHS Fast Approach state or the IHS Slow Approach state, depending on whether the workpiece position is known.</td>
</tr>
<tr>
<td>Homing</td>
<td>The lifter moves the torch up at the programmed IHS Speed till the Upper Limit Switch. For terminate homing procedure push on the TORCH UP or DOWN button.</td>
</tr>
<tr>
<td>Soft Limit</td>
<td>The THC enters this state when the actual position is the programmed Slide Length. The motor is stopped and the torch maintains its position. Only up motion is allowed during this state.</td>
</tr>
<tr>
<td><strong>IHS FAST APPROACH</strong></td>
<td>The torch moves down at the programmed Automatic Speed to the Start IHS Height then enters the IHS Slow Approach state. NOTE: For make next IHS on the slow speed (for example if cutting material was changed) - push on the TORCH UP and then DOWN buttons simultaneously when torch in zero position (“-Clr.” Message will issue).</td>
</tr>
<tr>
<td><strong>IHS SLOW APPROACH</strong></td>
<td>The lifter continues to move down at IHS Speed, using Ohmic or float head sensor, until the lifter receives the Tip Sense input signal. When the THC receives the Tip Sense input signal, it enters the Workpiece Contact state.</td>
</tr>
<tr>
<td><strong>WORKPIECE CONTACT</strong></td>
<td>The torch lifter begins to move up slowly until Ohmic sense or float head contact is clear. The lifter then records the workpiece position and enters the IHS Retract state.</td>
</tr>
<tr>
<td><strong>IHS RETRACT</strong></td>
<td>The lifter moves up at the programmed Automatic Speed to the Transfer Height.</td>
</tr>
<tr>
<td><strong>START PLASMA</strong></td>
<td>The lifter holds the torch at the IHS Transfer position, waits for the Transfer input signal from the plasma system, and then enters the programmed Pierce Start state.</td>
</tr>
<tr>
<td><strong>PIERCE START</strong></td>
<td>The lifter moves the torch to Pierce Height. When the torch is in position, the lifter enters the Piercing state.</td>
</tr>
<tr>
<td><strong>PIERCING</strong></td>
<td>The lifter holds the torch at the Pierce Height for the Pierce Delay interval. When Pierce Delay is complete, the lifter enters the Cut Prepare State.</td>
</tr>
<tr>
<td><strong>CUT PREPARE</strong></td>
<td>The lifter moves the torch to the Cut Height and sends to the CNC “Motion” signal to begin X/Y motion. The THC waits for the AVC Delay and then enters either the Sample state or the Cutting state, depending on the operating mode.</td>
</tr>
<tr>
<td><strong>CUTTING</strong></td>
<td>If AVC ON Mode is active and the THC OFF signal from the CNC is not active, the lifter controls the torch height using arc voltage feedback. If AVC OFF Mode is active operator can adjust the torch height by pushing on the Torch Up/Down buttons. When the cut is complete and the Cycle Start input signal from the CNC is deactivated, the THC enters the retract state.</td>
</tr>
<tr>
<td><strong>MANUAL UP</strong></td>
<td>The lifter initially jogs up 0.25 mm. After 0.5 second, it begins continuous upward motion at the IHS Speed. After 1.5 seconds, the lifter increases the speed to the programmed Manual Speed. Outputs do not change, if the torch is already cutting, it continues to cut.</td>
</tr>
<tr>
<td><strong>MANUAL DOWN</strong></td>
<td>The lifter initially jogs down 0.25 mm. After 0.5 second, it begins continuous downward motion at the IHS Speed. After 1.5 seconds, the lifter increases the speed to the programmed Manual Speed. The lifter does not change the output signals, if the torch is already cutting, it continues to cut.</td>
</tr>
<tr>
<td><strong>RETRACT</strong></td>
<td>The lifter moves the torch up at Automatic Speed to the Retract Height. When the torch is in position at the Retract Height and enters the Idle state.</td>
</tr>
</tbody>
</table>
Pre-Cut Setup

Before making a cut with the Neuron.THC system, perform the following setup sequence to ensure proper operation.

1. Edit the Set Point Voltage. Enter the recommended arc voltage for the material being cut.
   - Arc voltage control uses feedback from the plasma system to measure the voltage between the electrode (negative) and the plate (positive). At a given cut speed and fixed torch to work distance this voltage remains constant. If the plate is warped that it moves away from the torch during steady state cutting the arc between the electrode and the plate gets longer, a longer arc means the voltage gets higher. The torch height control sees an increase in arc voltage and signals the torch slide drive to move the torch closer to the plate.
   - If your torch height noticeably changes during the transition between cut height and AVC, then you should adjust your arc voltage setting so that there is no change during this transition. If the torch indexes to cut height, starts moving, then moves further away from the plate..., reduce the arc voltage setting. A rule of thumb is that 5 volts will equal approximately 1 mm (.020") torch movement, reducing arc voltage by 5 volts will move the torch closer to the plate by roughly 1 mm (.020") and increasing voltage will do the opposite.

2. Edit the Arc Transfer Height. Enter the recommended arc transfer height for the material being cut. If this data is not listed for thinner materials, try setting the arc transfer height to the same value as the pierce height. For thicker materials, try setting the arc transfer height to one-half the pierce height. Default Transfer height set to 150% from Cut Height.

3. Edit the Pierce Height. Enter the recommended pierce height for the material being cut. If this data is not listed for thinner materials, set the pierce height the same as the cutting height. For thicker materials, try setting the pierce height to 1.5 or 2 times the cutting height.

4. Edit the Cut Height. Enter the recommended cutting height for the material being cut. Things that affect torch height when operating in AVC (arc voltage control)
   - Gas pressure fluctuation. Changing gas pressure changes the resistance of the plasma arc, which changes the arc voltage.
   - Speed change. Slower cut speed makes the kerf wider, which means the arc is longer, which means the voltage is higher...so the THC moves the torch closer to the plate.
   - Worn electrode. Plasma electrodes wear by forming a pit in the hafnium emitter. If the pit is 1 mm deep, the torch will run closer to the plate by 1 mm, as the arc is 1 mm longer and the height control is trying to maintain a constant voltage.
   - The proper physical height is more important than setting the exact arc voltage that is listed in the plasma torch manufacturer’s manual. Adjust the voltage so the physical height is correct. Don’t worry about the voltage reading.

5. Edit the Pierce Time. Enter the recommended pierce time for the material being cut. The pierce time should be adjusted such that the torch moves from the pierce height to the cutting height after the arc pierces completely through the workpiece.

6. Edit the AVC Delay. This is delay before system starts controlling height using arc voltage. Set in second (0-10.0 sec).
   Hint: Set the delay long enough so cutting table is up to full cutting speed, torch has moved beyond cutting slag and arc voltage has stabilized. But don’t set the delay so long that the distance to the metal has changed from the initial cut height. To determine the correct setting, first determine how far you want the torch to move before turning on arc
Voltage control. Then considering the cutting speed, figure how long it takes the torch to move that far.

7. Edit Retract Height.
   - Sets the height the torch is raised (retracted) following end of a cut. For full retract to the top position select more than 60 mm (2.5 inches) value, that selection causes it to rise to the top.
   - At end of a cut, before moving to the next cut, torch is normally retracted to clear any obstructions such a part that tips up. Time is saved if a full retract is not required. **Hint:** If cutting small parts that may tip up or thin metal that is likely to spring up, set for higher retract to make sure the torch clears the cut piece. Use lesser amounts for larger pieces.

8. Edit Lock Head Down.
   - Sets voltage upper limit as percent (4-20%) of operating arc voltage.
   - When crossing a kerf or hole or going off the edge of the plate, arc voltage rises very rapidly. System will respond to the rise in voltage by lowering the torch trying to keep voltage constant. Without Lock Head Down torch will be driven into the plate. When voltage exceeds Lock Head Down setting, system stops trying to control height. Also refer to the Dynamic setting. **Hint:** For thicker metal which tend to be fairly flat and using lower cutting speeds the arc voltage doesn’t change very rapidly except when crossing kerfs & holes so using a lower % will respond quicker, typically 5-10%. For higher speeds on thinner or warped metal where normal cutting voltage changes more rapidly, use a higher number around 10-15% or even 20%.

   - Sets gain (response) of system (1-30). Factory setting of 7 is usually OK.
   - With thicker metal and lower cutting speeds where a faster response is not needed a lower Dynamic setting in combination with a lower Lock Head Down level %, can help prevent or limit torch diving when crossing kerfs or holes or when the part or scrap drops out before finishing the cut. 
   - Very high speeds on very thin or highly warped metal may require increasing the Dynamic setting to respond faster. Be careful to not go so high the torch overshoots and oscillates up and down. Remember you will generally want to go back to 7 normal cutting.

10. Place the system in the correct cutting modes desired (AVC ON/OFF, Set Point Voltage/Height).
11. Now a cut can be made with the Neuron.THC system. Verify the status of the LED’s on the cutting sequence LEDs during operation.
Sequence of Operation

1. Operator runs the work program by click on the “START” button on the CNC.
2. The CNC control move torch (x/y) to the IHS start position and wait the Motion signal from the controller. CYCLESTART command issue.
3. The torch travels towards the plate at Automatic speed and switches to the IHS Speed when the crossover “Start IHS Height” is reached. The torch touches the plate at the IHS Speed.
   **NOTE:** For make next IHS on the slow speed (for example if cutting material was changed) - push on the TORCH UP and then DOWN buttons simultaneously when torch in zero position (“-Clr.” Message will issue).
4. The torch immediately retracts to the Arc Transfer Height.
5. Plasma Start signal is issued to the plasma cutter.
6. Plasma cutter initiates an arc and the Neuron.THC receives an ArcOK (Transfer) signal from the power supply.
7. The torch moves to the Pierce Height and the Pierce Time timer is initiated.
8. When the Pierce Time elapses, the torch moves to the Cut Height.
9. The Neuron.THC issues a Motion signal to the x/y machine.
10. The x/y machine begins profiling the part.
11. The AVC Delay timer is initiated.
12. AVC Delay time starts. If sample voltage mode enabled (SET.H) THC is sampling the arc voltage, at end of AVC Delay. THC uses the last stable sampled voltage as a reference to control height for rest of cut. If sample mode is disabled (SET.U) THC uses the Set Point Voltage as a reference to control height.

13. THC start closed loop height control.

14. The Set Point Voltage, thus the torch height, can be increased and decreased while in AVC ON by “SP.Voltage +/-” buttons. AVC mode is disabled, thus freezing the torch height, any time a THC OFF signal is received (from CNC).

15. If AVC is disabled (AVC OFF) the torch height, can be increased and decreased by “Torch UP/DOWN” button. One click on the button will move torch on 0.25 mm (0.01 in).

16. If Lock Head Down is enabled, AVC mode is disabled any time a sudden increase in arc voltage is sensed, such as when crossing a kerf or running off the plate.

17. In any time operator can switch AVC ON/OFF mode by push on the “THC MODE” button. When switch to the AVC ON mode issue, controller re-sample real arc voltage and set it as Set Point Voltage for rest of cut.

18. If collision avoidance is enabled (provided that the Ohmic sensor is used), the arc voltage is automatically increased any time contact is sensed between the torch (ohmic sensor) and the plate, provided that the Ohmic function is enabled. If the torch contacts the plate while a AVC OFF or THC OFF signal is applied, the torch retracts to the programmed Cut Height.

19. When the Cycle Start signal is removed from the Neuron.THC, the torch retracts to the Full or programmed Partial Raise Height depending on the Retract Height value.

**Common cutting faults and Trouble-Shooting**

**Error codes**

*Note: for reset error state push on the “THC Mode” button. If in this time CYCLESTART signal present on the controller input – “Er.00” will issue. Deactivate the CYCLESTART input on the CNC interface to clear the error.*

| Er.17      | Slide Length Limit During Cut The lifter reaches a Slide Length limit during arc voltage controlled operation. | The lifter does not have the range of travel to accommodate the thickness of the material being cut.  
Solution: Adjust the lifter or torch mounting to make more effective use of the lifter travel range. |
| Er.18      | Arc Voltage PWM module Fault. Controller can work, but close loop control during cutting will be off (AVC OFF). | Fatal error. Arc voltage feedback module fault.  
Consult with manufacturer. |

### Possible Faults

<table>
<thead>
<tr>
<th>Fault</th>
<th>Possible causes</th>
</tr>
</thead>
</table>
| Transfer Fail | 1. Work cable connection on the cutting table is not making good contact.  
2. Torch-to-work distance is too high.  
3. The surface of the workpiece is rusty, oiled, or painted. |
| Failed to completely pierce the workpiece and there is excessive sparking on top of the workpiece. | 1. Current is set too low (check Cut chart information).  
2. Cut speed is too high (check Cut chart information).  
3. Torch parts are worn (change consumable parts).  
4. Metal being cut is too thick.  
5. The surface of the workpiece is rusty, oiled, or painted.  
6. Pierce Delay is set too low. |
| Dross forms on the bottom of the cut. | 1. Cutting speed is not correct (check Cut chart information).  
2. Arc current is set too low (check Cut chart information).  
3. Torch parts are worn (change consumable parts). |
| | 1. Wrong direction of machine travel. The high-quality side is commonly on the right with respect to the forward motion of the torch. |
USER'S MANUAL

| Cut angle is not square. | 2. Torch-to-work distance is not correct (check Cut chart information).  
3. Cutting speed is not correct (check Cut chart information).  
4. Arc current is not correct (check Cut chart information).  
5. Damaged consumable parts.  
6. The torch is not mounted perpendicular to the workpiece.  
7. Damaged torch. |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Short consumable life. | 1. Arc current, arc voltage, travel speed, motion delay, gas flow rates, or initial torch height was not set as specified in the cut charts.  
2. Attempting to cut highly magnetic metal workpiece, such as one with a high nickel content, will shorten consumable life. Long consumable life is difficult to achieve when cutting a workpiece that is magnetized or becomes magnetized easily.  
3. Beginning or ending the cut off the surface of the workpiece. To achieve consumable long life, all cuts must begin and end on the surface of the workpiece. |
| Part is the wrong size.| The Kerf value is set incorrectly. |

How to optimize cut quality

The following tips and procedures will help produce square, straight, smooth and dross-free cuts.

**Tips for table and torch:**
- Use a square to align the torch at right angles to the workpiece.
- The torch may travel more smoothly if you clean, check and “tune” the rails and drive system on the cutting table.
- Unsteady machine motion can cause a regular, wavy pattern on the cut surface.
- The torch must not touch the workpiece during cutting. Contact can damage the shield and nozzle, and affect the cut surface.

**Plasma set-up tips**

Follow carefully each step in the operating cycle for each operating mode, described earlier in this section. Purge the gas lines before cutting.

**Maximize the life of consumable parts**

The long life requires that cuts start and stop on the workpiece.  
- The torch should never fire into the air.  
  - Start the cut at the edge of the workpiece is acceptable, as long as the arc is not fired in the air.  
  - To start with a pierce, use a pierce height that is 1.5 to 2 times the torch-to-work distance.  
- Each cut should end with the arc still attached to the workpiece.  
  - When cutting drop parts (small parts that drop down after being cut from the workpiece), check that the arc stays attached to the edge of the workpiece.

Note: Use a continuous cut between parts if possible, so the path of the torch can lead directly from one cut part into the next, without stopping and starting the arc. However, do not allow the
path to lead off the workpiece and back on, and remember that a chain cut of long duration will cause electrode wear.

**Additional factors of cut quality**

**Cut angle**
A cut part whose 4 sides average less than 4° of cut angle is considered acceptable.  
Note: The squarest cut angle will be on the right side with respect to the forward motion of the torch.  
Note: To determine whether a cut-angle problem is being caused by the plasma system or the drive system, make a test cut and measure the angle of each side. Next, rotate the torch 90° in its holder and repeat the process. If the angles are the same in both tests, the problem is in the drive system.  
If a cut-angle problem persists after “mechanical causes” have been eliminated check the torch-to-work distance, especially if cut angles are all positive or all negative.  
• A positive cut angle results when more material is removed from the top of the cut than from the bottom.  
• A negative cut angle results when more material is removed from the bottom of the cut.
Dross

What is dross?

Dross is molten metal that does not blow away during the cutting process and instead adheres to the bottom or top of the part in a re-solidified state. There are many factors that can contribute to the accumulation of dross. The most common are: cutting speed, torch standoff height or damaged consumables. In most instances, dross can be reduced or eliminated completely by adjusting the cutting speed to the optimum condition as prescribed in the operator’s manual. However, there may be times when a simple speed adjustment is not possible or will have little effect, such as when the thickness of the material or the cutting amperage requires a slow cutting speed. In this case, dross accumulation is inevitable and cannot be eliminated. Also, the quality, grade and composition of the material are factors that can increase the likelihood of dross and are outside of the control of cutting parameters. For example, a lower quality sheet of carbon steel may be more susceptible to dross buildup due to the increased level of impurities. Finally, as the temperature of the plate increases from the plasma cutting process, dross is more likely to stick to the bottom even with optimum parameters.

High Speed Dross

Cause:
When the programmed cutting speed is too fast for the amperage being used or the material thickness being cut, the bottom of the arc will lag behind the top. When this happens, the high pressure gas found at the orifice of the nozzle is not as effective at material removal, allowing small amounts of dross to form on the bottom of the plate. High speed dross is typically dotted in appearance and cannot be removed easily by scraping with a hand tool. It must be removed by grinding or machining the finished part.

Solution:
Verify the cutting speed for the selected amperage, material type and thickness. If it already does, decrease the cutting speed in small increments (5-10 inches per minute) until the best result is achieved.

Select a lower cutting amperage

Examine the electrode and nozzle for excessive wear and replace as needed.
Low Speed Dross

Cause:
If the cutting speed is too slow for the material thickness or selected amperage, a solid line of dross that resembles a weld bead will form on the bottom of the part. To understand why, remember that the plasma cutting process is electrical in nature. When the torch is moving too slowly, the arc begins to expand in an effort to maintain contact with the edge of the kerf in order to keep its path to ground through the plate. As the arc widens, the distance from the cut edge to the high pressure section of the plasma jet increases to the point where the gas is no longer able to blow away the material effectively. Low speed dross is easily removed with a hand scraping tool.

Solution:
Verify the cutting speed for the selected amperage. If it already does, increase the cutting speed in small increments (2-5 in. per minute) until the best result is achieved.

Select a higher cutting amperage and adjust the parameters accordingly.

Examine the nozzle and shield cap for damage and replace as needed.
**Corner Dross**

*Cause:* Dross will intermittently form in the corners of a part due to the speed reduction required for a cutting machine to perform an extreme change in direction, such as a right angle. The likelihood of this occurring varies depending on the thickness of the material, cutting amperage, and material composition.

*Solution:* This is a normal occurrence and cannot be avoided without altering the part drawing to include options such as corner loops.

Fortunately, the amount of dross this condition presents is minimal and is easily removed with a hand scraping tool.

**Top Dross**

*Cause:* Occasionally, small amounts of dross will form on the top of the part when the programmed cutting speed is too fast or the torch standoff distance is too high. This is caused by the plasma arc’s inability to blow all the molten metal through the bottom of the kerf when the tip of the
nozzle is too high above the plate. Top dross is normally a very light accumulation that can be removed easily with a scraping tool.

**Solution:**
1. Reduce cutting speed in 5 in. per minute increments, while monitoring for the introduction of low speed dross.
2. Lower the arc voltage setting in 2 volt increments.
3. Check the nozzle for damage and replace as needed.

**Additional improvements**

Some of these improvements involve trade-offs, as described.

**Piercing**
The pierce delay should allow sufficient time to penetrate the full thickness of the material, but not so long that it allows the arc to “wander” while trying to find the edge of a large pierce hole. As consumables wear, this delay time may need to be increased. Pierce delay times given in the cut charts are based on average delay times throughout the life of the consumables.

When piercing materials close to the maximum thickness for a specific process, there are several important factors to consider:
- Allow a lead-in distance that is about the same as the thickness of the material being pierced. 50 mm (2 in) material requires a 50 mm lead-in.
- To avoid damage to the shield from the buildup of molten material created by the pierce, do not allow the torch to descend to cut height until it has cleared the puddle of molten material.
- Different material chemistries can have an adverse effect on the pierce capability of the system. In particular, highstrength steel and steel with a high manganese or silicon content can reduce the maximum pierce capability.
- Starting torch motion immediately after transfer and during the pierce process can extend the piercing capability of the system in some cases. Because this can be a complex process that can damage the torch or other components, a stationary or edge start is recommended.
How to check cutting speed and arc current for cut quality

Decrease the torch-to-work distance. This will increase the negative cut angle. Note: The torch must not touch the workpiece while piercing or cutting.

The thin lines are almost straight and at an angle of 15-30 degrees. 
**The cutting speed and Arc current is correct.**

![Image of straight lines at an angle](image1)

Lines are not straight and have a curved form in the upper part and further parts directed vertically as shown in Figure. 
**The cutting speed is low. Increase the cutting speed.**

![Image of curved lines](image2)

Lines are not straight and have a curved form in the lower portion of the part as shown. 
**The cutting speed is too high or arc current is too low.**
